Ginsenosides from *Panax ginseng* are well known for their diverse pharmacological effects including anti-thrombotic activity. Since adventitious roots of mountain ginseng (ARMG) also contain various ginsenosides, blood flow-improving effects of the dried powder and extract of ARMG were investigated. Rats were orally administered with dried powder (PARMG) or ethanol extract (EARMG) of ARMG (125, 250 or 500 mg/kg) or aspirin (30 mg/kg, a reference control) for 3 weeks. Forty min after the final administration, carotid arterial thrombosis was induced by applying a 70% FeCl₃-soaked filter paper outside the arterial wall for 5 min, and the blood flow was monitored with a laser Doppler probe. Both PARMG and EARMG delayed the FeCl₃-induced arterial occlusion in a dose-dependent manner, doubling the occlusion time at high doses. In mechanism studies, a high concentration of EARMG inhibited platelet aggregation induced by collagen *in vitro*. In addition, EARMG improved the blood lipid profiles, decreasing triglyceride and cholesterol levels. Although additional action mechanisms remain to be clarified, it is suggested that ARMG containing high amount of ginsenosides such as Rg₃ improves blood flow not only by inhibiting oxidative thrombosis, but also by modifying blood lipid profiles.

Keywords: Mountain ginseng, adventitious root, ginsenoside, platelet aggregation, blood flow

Received 12 December 2016; Revised version received 7 February 2017; Accepted 16 March 2017

Today, cardiovascular diseases (CVD) due to hypertension, hyperlipidemia, and atherosclerosis are one of the largest contributors to global mortality, leading to death of 19.5 million people in 2016. According to the World Health Organization, it will be about 23.3 million deaths from CVD in 2030 [1]. As the lifestyle of modern society has changed, high-energy and fat-rich diet, stresses, crapulence, and reduced exercise are believed to cause increased cardiovascular risks by affecting lipoprotein metabolism, platelet aggregation ability, and vessel resistance. It is well established that the incidence of CVD is due to hyperlipidemia, a condition characterized by significant increases in total cholesterol (TC), triglycerides (TG), and low-density lipoproteins (LDL) as well as decrease

in high-density lipoproteins (HDL) [2,3].

Aspirin is a widely used anti-thrombosis drug for preventing cardiovascular diseases. Low doses of aspirin have been shown to have a preventive effect on thrombus formation in animal experiments [4]. But aspirin is acidic and stimulates stomach to release gastric acid. Besides, it affects gastric wall to become weak and causes gastric hemorrhage. In addition, currently available anti-thrombotic agents such as tissue-type plasminogen activator (t-PA), streptokinase, and PA-type agents for clinical research have some adverse-effects [5]. Therefore, safe and effective anti-thrombotic agents that can inhibit thrombosis are needed to be studied. Medicinal plants are the attractive source of pharmacologically active

compounds and agents.

Panax ginseng C.A. Meyer is well known as the most important botanical medicine in traditional eastern Asia for longer than 2000 years, and now one of the most extensively used herbal products in the world [6,7]. The root of *Panax ginseng* has long been studied for its pharmacological efficacies [8]. In Korea, mountain ginseng, wild *Panax ginseng* which lives in mountain naturally, has been considered traditionally more effective than cultivated ginseng products [9]. This plants grow wild in cool, shady forests from Korea and north eastern China to far eastern Siberia [8,10,11]. Mountain ginseng has become extremely scarce and the ginseng supply depends almost solely on field cultivation, which is a time-consuming and labor-intensive process. However, tissue culture techniques for mountain ginseng have been established by bioreactor technology as a useful tool for large-scale production of root biomass [12,13]. Tissue culture techniques allowed us to easily obtain a mass of adventitious roots.

Tissue-cultured mountain ginseng was produced to contain higher concentration of bioactive ginsenosides or polyphenols than cultivated ginseng; these compounds are believed to be beneficial to human health [14]. The major active ingredients of ginseng are the triterpene glycosides named ginsenosides, which have been studied extensively for their pharmacological effects. These saponins possess diverse pharmacological actions for treating various diseases including cerebral ischemia [15], hypertension [16], and symptoms of hyperlipidemia [17], in addition to anti-fibrotic and antioxidant activities [18,19], which are associated with circulatory system or others as well. Polyphenols rich in mountain ginseng defend tissues from radical damage and have anti-cholesterol, intestinal regulatory, anti-cancer, and antioxidant effects [20].

Based on the reported biological effects, we suggested that the adventitious root of mountain ginseng (ARMG) would influence physiological hemostatic and pathological thrombotic processes. The present study was designed to investigate whether dried powder (PARMG) and an extract (EARMG) of ARMG have potential anti-thrombotic activity, in addition to underlying mechanisms, when it was taken orally.

Materials and Methods

Materials

The experimental materials, PARMG and EARMG treated with methyl jasmonate (50 μ M) for 2 days were obtained from Dongkook Pharmaceutical Co., Ltd. (Seoul, Korea), and kept at 4°C until use. After steaming, PARMG was extracted with 70% ethanol to obtain EARMG. PARMG, EARMG or aspirin was orally administered in a volume of 10 mL/kg sterile purified water. Aspirin, a reference material, was used as a well-known blood flow enhancer.

Animals

Seven-week-old male Sprague-Dawley (SD) rats were from Daehan-Biolink (Eumseong, Korea), and subjected to the experiment after acclimation to the laboratory environment for 1 week. The animals were housed in a room with constant environmental conditions (temperature: 22 \pm 2°C, relative humidity: 40-70%, light-dark cycle: 12 hours, brightness: 150-300 lux, ventilation: 12 times/hour), and provided with purified water and rodent pellet diet *ad libitum*. All the animal experiments were approved by the Institutional Animal Care and Use Committee (IACUC) of Chungbuk National University (CBNU), Korea (Approval number: CBNUA-974-16-01), and conducted according to the Standard Operation Procedures (SOP) of Laboratory Animal Research Center (LARC) of CBNU.

Measurement of platelet aggregation

Blood sample was withdrawn from the male SD rats directly into anti-coagulant citrate dextrose solution containing 0.8% citric acid, 2.2% trisodium citrate, and 2% dextrose. Washed platelets were prepared as previously described [21]. In brief, platelet-rich plasma (PRP) was obtained by centrifugation at 170 *g* for 7 min. Platelets were sedimented by centrifugation of the PRP at 350 *g* and washed with tyrode buffer. The washed platelets were resuspended in tyrode buffer and adjusted to 3 \times 10⁸ platelets/mL [22,23].

Platelet aggregation was measured with an aggregometer (Chrono-Log Co., Harbertown, CA, USA) according to the turbidimetric method of Born and Cross [24]. The

washed platelet suspension was pre-incubated with PARMG, EARMG or aspirin (125, 250 or 500 µg/mL) at 37°C in the aggregometer under stirring at 1,200 rpm. After 3-min pre-incubation, platelet aggregation was induced by adding collagen (0.625 µg/mL), adenosine diphosphate (ADP, 10 µM) or thrombin (0.1 unit/mL). The extent of aggregation was expressed as percentage of the vehicle control value stimulated with collagen, thrombin or ADP.

Measurement of blood flow

Rats (n=8/group) were orally administered with PARMG, EARMG (125, 250 or 500 mg/kg) or aspirin (30 mg/kg) for 3 weeks. Forty min after the final administration, the animals were anesthetized by intramuscular injection of urethane (1 g/5 mL/kg), under constant maintenance of body temperature (36-37°C) using a heating pad. The right carotid artery of rats were exposed and detached away from the vagus nerve and surrounding tissues. Aortic blood flow rate was monitored with a laser Doppler flowmeter (AD Instruments, Colorado Springs, CO, USA). At the time point of 1 hour after the final administration, arterial thrombosis was induced by wrapping the artery with a Whatman No. 1 filter paper (3×5 mm) soaked with 70% FeCl₃ solution near (5 mm anterior to) the flowmeter probe for 5 min. The blood flow was monitored for 40 min, and the time to occlusion was recorded. Animals were sacrificed at the time point of 40 min from the application of FeCl₃, and the arteries were cut to observe the thrombus in the artery.

Thrombus weight and histopathology

After 40-min monitoring of the blood flow in carotid artery applied with 70% FeCl₃ to the external surface, the arteries were cut at intervals of 1 mm from the visible thrombus regions. Then, the length (in mm) and weight (in mg) of the thrombotic arteries were measured.

For microscopic examination, an 1.5-cm section of the ascending thoracic aorta was dissected from the heart. The injured artery was fixed in 4% paraformaldehyde, and embedded in paraffin. Paraffin sections were cut (4 µm in thickness), and stained with hematoxylin and eosin. The proportion of platelet plug to whole blood clot in cross-sectional area of the vessels was analyzed using an ImageJ 1.46b image analysis software.

Hematology and blood biochemical analysis

After 16-hour overnight fasting (feed only), blood samples were collected from rats orally administrated with PARMG, EARMG or aspirin for 3 weeks. Complete blood cell counts (CBC) were measured with an automatic hematology analyzer (INTEGRA 400; Roche, Mannheim, Germany).

Blood samples were centrifuged at 3,000 g for 15 min at 4°C. Biochemical analysis was performed in sera using a blood chemistry analyzer (Hitachi-747; Hitachi Korea, Seoul, Korea) for lipids including total cholesterol (TC), low-density lipoproteins (LDL), high-density lipoproteins (HDL), and triglycerides (TG) as well as glucose.

Statistical analysis

All data are expressed as a mean±standard error (SE). Statistical significance was analyzed using SPSS package (version 18.0; SPSS Inc., Chicago, IL, USA). Differences among groups were compared with one-way ANOVA, followed by Dunnett's multiple-range test. *P*-value <0.05 was considered to be statistically significant.

Results

PARMG did not inhibit all the collagen (0.625 µg/mL)-, ADP (10 µM)- or thrombin (0.1 unit/mL)-induced platelet aggregation up to 250 µg/mL (Figure 1). However, the significant inhibition on the collagen-induced platelet aggregation at a higher concentration (500 µg/mL) is unclear, since turbid PARMG interfered with the analysis of platelet aggregation. In comparison, a high concentration (500 µg/mL) of EARMG markedly inhibited the collagen-induced platelet aggregation to a half level, although it did not affect the ADP- and thrombin-induced aggregation. Similar results were attained by aspirin (500 µg/mL), near-fully inhibiting only collagen-induced platelet aggregation.

During whole 3-week administration period of PARMG, EARMG or aspirin, there were no abnormal symptoms in rats, and the rats gained body weights steadily in normal state.

Five-min application of 70% FeCl₃ outside carotid arterial wall caused gradual decrease in the blood flow that near-fully ceased in 30 min (Figure 2). However, 3-week oral treatment with PARMG inhibited the thrombus

Figure 1. Inhibition of platelet aggregation by dried powder (PARMG) or ethanol extract (EARMG) of adventitious roots of mountain ginseng or aspirin. Platelet aggregation was induced by collagen (0.625 μg/mL; A), adenosine diphosphate (ADP, 10 μM; B) or thrombin (0.1 unit/mL; C). Virgule: 125 μg/mL, gray: 250 μg/mL, black: 500 μg/mL. *Significantly different from vehicle controls (collagen, ADP or thrombin alone).

formation in a dose-dependent manner, in which the blood flow was maintained longer than 40 min in the rats treated with a high dose (500 mg/kg) of PARMG, as observed in rats treated with aspirin (30 mg/kg) (Figure 2A). EARMG also delayed the arterial obstruction in a dose-dependent manner (Figure 2B). The mean occlusion time in the vehicle control group was calculated to be 18.1 min, based on the time point when the blood flow

Figure 2. Time-course of carotid arterial blood flow following FeCl₃ application outside the arterial wall. Dried powder (PARMG; A) or ethanol extract (EARMG; B) of adventitious roots of mountain ginseng or aspirin (A & B) were orally administered for 3 weeks prior to FeCl₃ exposure. ●: vehicle (FeCl₃ alone) control, ▼: low dose (125 mg/kg) of PARMG or EARMG, ■: medium dose (250 mg/kg) of PARMG or EARMG, ◆: high dose (500 mg/kg) of PARMG or EARMG, ▲: aspirin (30 mg/kg).

dropped to 10% (practical cessation) of initial flow rate (Figure 3). However, PARMG markedly prolonged the occlusion time to 25.8, 30.9, and 34.4 min at 125, 250, and 500 mg/kg, respectively. Similar effects were achieved with EARMG, extending the occlusion time to 19.4, 31.7, and 34.7 min at 150, 250, and 500 mg/kg, respectively. Such a blood flow-improving activity was also attained by aspirin (30 mg/kg) that prolonged the occlusion time to 39.4 min.

Forty min after FeCl₃ exposure, thrombi weighing 0.83 mg/mm were formed (Table 1). The thrombus weight decreased following treatment with PARMG, leading to a significant reduction to 0.72 mg/mm at 500 mg/kg. Such significant decreases in the thrombus weight were also achieved with EARMG (125 and 500 mg/kg) and aspirin (30 mg/kg).

Dried powder (PARMG) or ethanol extract (EARMG) of adventitious roots of mountain ginseng or aspirin were orally administered for 3 weeks prior to FeCl₃ exposure. *Significantly different from vehicle (FeCl₃ alone) control ($P < 0.05$).

Table 1. Thrombus weight in the carotid arteries after application of FeCl₃ outside the arterial wall

Treatment	Dose (mg/kg)	Thrombus (mg/mm)
FeCl ₃ alone	0	0.83±0.03
PARMG	125	0.78±0.03
	250	0.78±0.01
	500	0.72±0.03*
EARMG	125	0.73±0.04*
	250	0.81±0.07
	500	0.76±0.01*
Aspirin	30	0.76±0.03

Dried powder (PARMG) or ethanol extract (EARMG) of adventitious roots of mountain ginseng or aspirin were orally administered for 3 weeks prior to FeCl₃ exposure. *Significantly different from vehicle (FeCl₃ alone) control ($P < 0.05$).

As dissected 40 min after exposure to FeCl₃, the arteries were entirely plugged with thrombi in the vehicle-treated rats (Figure 4). In the analysis of the thrombus, it was composed of 82.5% blood clot and 17.5% platelet plug (Figure 5). In the animals treated with PARMG, EARMG or aspirin, the thrombi were loose and had larger portions of permeable platelet plugs, relative to the flow-blocking blood clots. That is, aspirin (30 mg/kg) enhanced the portion of platelet plugs to 52%. By comparison, PARMG (500 mg/kg) increased the platelet plug ratio to 40%, and EARMG (500 mg/kg) also expanded to 43%.

In the blood biochemical analysis, PARMG (125-250 mg/kg) reduced blood TC, HDL, and TG levels, although there was no dose-response relationship (Table

2). EARMG significantly decreased blood glucose level at all doses tested (125-500 mg/kg), and lowered the lipids at a high dose (500 mg/kg). In comparison, aspirin (30 mg/kg) reduced TC, HDL, and TG.

Discussion

This study was designed to investigate whether PARMG and EARMG have anti-thrombotic potential when it was taken orally. Furthermore, we attempted to find out which state of ARMG (dried powder or ethanol extract) is more effective for blood flow improvement via *in vitro* platelet aggregation assay as well as *in vivo* FeCl₃-induced carotid arterial thrombosis model.

A high concentration (500 µg/mL) of ARMG significantly inhibited the collagen-induced platelet activation, in which EARMG was more potent than PARMG. Collagen fibers are exposed to circulating platelets following damage to the vessel wall and play an important role in hemostasis through the creation of a physical barrier at the site of vascular injuries, thereby limiting blood loss [25-27]. The collagen fibers also stimulate platelet activation, recruiting additional platelets to the site of damage as well as consolidating the thrombus [27].

Many studies have reported the anti-platelet activity of ginsenosides [28,29]. It is suggested that the major ginsenosides in ARMG should be effective in inhibiting collagen that induces platelet aggregation. Platelet activation is characterized by shape change, granule secretion, and ultimately, aggregation. These responses are triggered by

Figure 4. Representative findings of carotid arterial thrombi produced by FeCl₃ application outside the arterial wall. Dried powder (PARMG) or ethanol extract (EARMG) of adventitious roots of mountain ginseng or aspirin were orally administered for 3 weeks prior to FeCl₃ exposure. Gray aggregated platelet plugs (empty star) and yellow/pink blood clots (filled star) are seen in the arterial lumens exposed to FeCl₃.

Figure 5. Platelet plug (gray) and blood clot (black) ratios in the carotid arterial thrombi produced by FeCl₃ application outside the arterial wall. an increase in intracellular Ca²⁺, which is induced by collagen [30,31]. Thus, the inhibition of this increase in [Ca²⁺]_i blocks the collagen-induced aggregation of human platelets [31]. The inhibitory effect of ARMG on the collagen-induced aggregation may be involved in the inhibition of Ca²⁺ influx by decreasing thromboxan A₂

(TXA₂) formation. At lower concentrations, many of the effects of collagen are enhanced by its production of TXA₂ [32-35]. The collagen-induced increase in [Ca²⁺]_i can be blocked by inhibiting the production of TXA₂ via the pretreatment of platelets with cyclooxygenase inhibitors such as aspirin [30,36,37]. It was reported that the anti-platelet aggregation effect of ginseng may be due to the decreased production and release of TXA₂ [28]. Therefore, a part of the mechanisms involved in calcium mobilization and TXA₂ release would be needed for further understanding of the processes whereby collagen induces platelet aggregation as well as PARMG and EARMG inhibit the process.

In the present study, the anti-thrombotic activities of PARMG and EARMG were evaluated in a FeCl₃-induced carotid arterial thrombosis model. This model is widely used to study thrombogenesis *in vivo*. Since transition metals such as ferric ion facilitate oxidative radical formation, lipid peroxidation of cellular and tissue injuries as well as endothelial cell damage that leads to occlusive thrombus formation [38]. As shown in Figure 2 and Table 1, oral administration of PARMG and EARMG significantly delayed the occlusion time in a dose-dependent manner, indicating that the adventitious

roots of mountain ginseng was able to inhibit thrombus formation *in vivo* and possibly act as platelet aggregation inhibitors like aspirin.

In the model of FeCl₃-mediated rat artery thrombosis, the thrombi are composed of fibrin, activated platelets, and entrapped erythrocytes. Clinically, this type of thrombus is found in the coronary arteries after sudden death and acute myocardial infarction [39,40]. Fibrin polymers and fibrin clots as the major components of thrombus are made from fibrinogen via the enzymatic action of thrombin. In the present study, the thrombi were observed to be separated into loose platelet plugs and compact blood (fibrin) clots. Notably, PARMG, EARMG as well as aspirin decreased the portion of impermeable blood clots, increasing the permeable platelet plugs. Such effects on the ratio of platelet plug/fibrin clot suggest that blood flow-improving compounds have an ability to change the structure or composition of fibrin network. As demonstrated *in vitro* platelet aggregation assay and *in vivo* thrombus analysis, ARMG may interrupt the early stage of hemostasis triggered by collagen, rather than that induced by thrombin. Thus, it is supposed that following interference with initial hemostasis, relatively-loose platelet adhesion remained, leading to decrease in the strong blood clot formation. So, this may make the blood vessel obstructs slowly. On the other hand, the interaction between fibrin structure and coagulation factors is a complex process, and it has been reported that the composition of fibrin structure affects its sensibility to enzymatic activity of thrombin [41]. Thus, it is suggested that PARMG and EARMG suppress fibrin clotting by interrupting the interaction between fibrinogen and thrombin or by decreasing the thrombin activity in the body environment.

In biochemical analysis, PARMG and EARMG improved the blood lipid profiles. In addition, EARMG remarkably decreased the glucose level. It was previously reported that there was a significant decrease in TG level in diabetic rats fed with the extracts of tissue-cultured adventitious roots of mountain ginseng [42]. Such an effect was also achieved in a human study [43], wherein ginsenosides stimulated lipid metabolism in diabetic individuals. Therefore, the beneficial efficacies of ARMG on the blood lipid and glucose levels may attract attentions of investigators and practitioners.

The major components of ginseng are saponins called ginsenosides. Ginsenosides are well known for cardio-protective, immuno-stimulatory, anti-fatigue, and hepato-protective activities [44]. According to some studies, ginsenosides are the main components affecting the hemostatic and thrombotic processes [45,46]. Among various ginsenosides, it was reported that both Rg₁ and Rg₂ have an anti-thrombosis activity [47]. Notably, Rg₃ is the most potent ginsenoside in inhibiting platelet aggregation by decreasing TXA₂ formation and granule secretion in platelets, which are mediated by Ca²⁺ influx and Ca²⁺ mobilization from intracellular stores [48].

Interestingly, the tissue-cultured ARMG contained higher amounts of Rb₁, Rb₂, Rc, Rd, Re, Rg₁, and Rf ginsenosides when compared to field cultivated Korean ginseng. In addition, ginsenosides such as Rb₃, Rg₂, Rg₃, Rh₁, and Rh₂ which were lacking in the extracts of field-cultivated Korean ginseng were abundant in ARMG [42]. Notably, it is well known that higher amounts of original ginsenosides and other novel ginsenosides are accumulated by treatment with methyl jasmonate during the tissue culture which is not contained process in Korean ginseng field cultivation [12]. It was reported that

methyl jasmonate stimulates the ginsenoside biosynthetic pathway, thus enhancing the accumulation of ginsenosides up to 5-7 folds in adventitious roots [49,50]. Besides, it seemed that steaming and extraction processes of ARMG led to different concentrations of ginsenosides. In contrast to the low concentration of Rg₃ in PARMG (0.18 mg/g), that in EARMG was 0.43 mg/g, implying that various ginsenosides including Rg₃ can be more obtained during processes of ginseng products. In the present study, EARMG was somewhat superior to PRAMG in the anti-thrombotic activity which might be due to the increased ginsenosides including Rg₃.

Taken together, ARMG, especially EARMG, improved blood flow by inhibiting platelet aggregation induced by collagen as well as thrombus formation induced by oxidative vascular injury. Although more actual mechanisms remain to be clarified, the adventitious roots of mountain ginseng would be good natural candidate without adverse effects for the prevention and improvement of cardiovascular and cerebrovascular diseases.
